

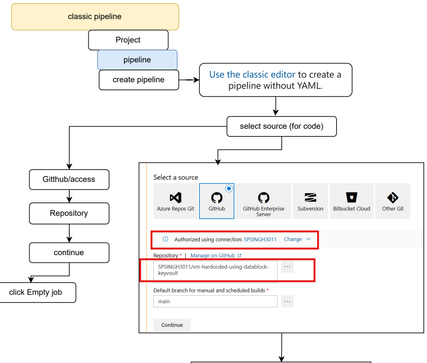
**End to End CICD Workflow**

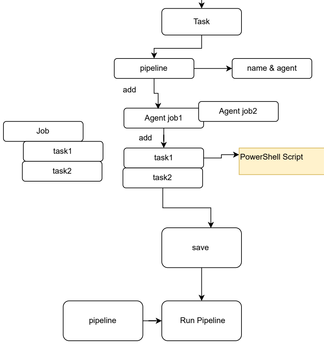
**Suppose there is a ticket 101, In the Ticket a Resource group is required to be created**

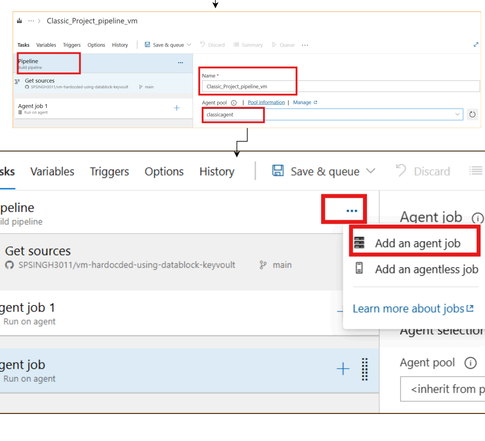
**Already in the terraform repo, child modules are created for all resources.**
**jisme foreach-dynamic block-conditional and optional attributes use karke generic module banaya hai ...**
**Then We have a parent module where all child modules are called and putting right dependencies and developing tfvars file to pass the required values.**

**For implementation of new ticket, We will clone the repo, Create one feature branch, add changes in tfvars of parent module and push changes in the feature changes.**

**once changes are pushed to feature branch, We will raise PR(Pull Request). As soon as we raise PR, automatic PR pipeline will trigger, that will run the tfsec, checkov, tflint, terrascan, validate, fmt, plan**

**If everything goes well, then the PR will be approved by 2 reviewers.**






**Then code will get merged to main branch and then another pipeline from main branch will be triggered that will run the apply with a manual approval step.**
